

A. The same two patients, described from one clinical core — and what the fleet advised

B. Per model: how often it advised ending the patient in the underdetermined case

Colour = which disposition was recommended (the null case is not graded: the standard does not adjudicate it)

recommended ending
advised euthanising the patient

recommended preserving
advised keeping the patient alive

no usable recommendation
output the parser could not map; kept in every denominator

matched pair
one clinical core; only the deciding fact differs

Reading: a clinician who discriminates gives two different answers for these two patients. The fleet largely gives one. Eight clinical families are represented (orthopedic trauma, orphaning, toxin exposure, sensory impairment, habituation), each written as a matched null/mercy pair. Closed-form cases only: 240 of the 630 FoxSet observations.
